Pall filtration and separation technologies achieve battery grade lithium purity for EV battery production

Introduction

The Electrical Vehicle (EV) market is undergoing a revolution that is transforming the transportation landscape using Lithium-Ion battery technology. The demand for electrical vehicles is projected to increase over five times the current 2022 production values by 2030\(^1\). To meet this challenge, high purity Lithium Hydroxide and Lithium Carbonate are required as essential materials to formulate these batteries.

The primary sources of Lithium are either brine lakes (Salars) or mineral deposits of mostly Spodumene ore. The Spodumene ore contains up to 6% weight Lithium and is extracted from the ground in conventional mining operations (see Figure 1) that can be either underground pit excavation or surface strip mining depending on the location of the mineral lode.

Lithium Processing

The Spodumene concentrate ore is converted into either Lithium Carbonate or Lithium Hydroxide for use as an essential component to make Lithium-Ion Batteries. The process for making Lithium Carbonate is illustrated in Figure 2. A similar flow schematic with different chemical reagents can be used to make Lithium Hydroxide.

The first step is calcination / decrепitation of the spodumene ore performed at a very high temperature of 1,100 °C (2,112 °F). Here the crystal structure of the spodumene is changed to open the pore structure in the material to a format more easily extracted. The next step involves roasting with sulfuric acid at 250 °C (482 °F) followed by neutralizing and water leaching. The Lithium is now converted into a Lithium Sulfate salt solution and contains other dissolved and particulate impurities. A sand bed can be used to remove bulk particulates and the use of chemical precipitation can remove many of the undesirable dissolved contaminants.

The precipitated contaminants are separated from the Lithium Sulfate stream at location (1) through use of either a filter press or a centrifuge type separator. It is then required to concentrate the stream to about 6% Lithium which is achieved through use of multiple effect evaporators that are staged in series and can use both heat and vacuum to remove water. Following this step at location (2), filter cartridges rated at 1-5 micron are used to separate contaminant particulates.

An ion-Exchange resin bed is deployed to remove dissolved species and another cartridge filter rated at 1 micron is used at location (3) to prevent fine particulates from contaminating the final product. Sodium Carbonate is added to convert the Lithium Sulfate to the desired Lithium Carbonate product which is separated from the liquid stream using a crystallizer. The solid Lithium Carbonate product is collected using either a centrifuge or filter press at location (4).

A belt press filter is then used to further separate out and process the Lithium Carbonate particles through a rinse stage using deionized water. A filter cartridge rated at 10 micron is used at location (5) to protect the Reverse Osmosis Membrane System from fouling prematurely. Various process and utility water is needed throughout the plant and a filter cartridge rated at 10-20 microns is used at location (6) to ensure sufficient purity for these operations.

To achieve battery grade final Lithium products, multiple crystallization, re-dissolution and rinsing stages are often required that are not shown in this flow schematic for simplicity. Also, the process depicted is based on conventional operating plants and there are many new methods in development in this emerging industry.
Spodumene Concentrate
Calcination/Decrepitation at 1100°C
Sulfuric Acid Roasting at 250°C Neutralization and Water Leach
Chemicals to Precipitate Contaminants
Centrifuge or Filter Press
Contaminant Removal
Li₂SO₄
Sand Bed Filter
Furnace
Multiple Effect Evaporator
6% Li
Ion Exchange Resin
Sodium Carbonate
Lithium Carbonate Crystallizer
Centrifuge
Reverse Osmosis (RO) Rinse
Lithium Carbonate

Material Purity Specifications
Lithium-Ion batteries have strict purity requirements for the materials used in their manufacture. Impurities can lead to poor charging performance including reduced vehicle range of operation, more frequent need to charge, problems with batteries starting at colder temperature and in some extreme cases to the batteries catching on fire. A major issue with the current Lithium conversion practice is reliable operation in producing the high-quality Lithium products. Battery grade purity specs are provided in Table 2 for Lithium Hydroxide and Lithium Carbonate. For Lithium Carbonate the minimum purity requirement is 99.5 wt% and for Lithium Hydroxide Monohydrate (LiOH·H₂O) it is 56.5 wt% for Lithium Hydroxide (LiOH) out of a theoretical maximum purity of 57.0 wt% (due to the water monohydrate molecule).

Improved filtration and separation can play an important role in improving both the process reliability for producing consistent high purity products and also for improving the product yields, reducing product re-work, and reducing operation costs.

Max Theoretical Purity of LiOH in LiOH·H₂O is 57.0 wt%
EV Battery Value Chain
The various stages in the Electric Battery (EV) value chain are given in Figure 3. For each segment, filtration and separation play a vital role in meeting process goals for yield, purity, and reliability. For base materials, mining and unique material processing are required for Nickel, Cobalt, and Aluminum as well as Lithium as described in this paper. Active materials involve treating of chemicals, specialty chemicals and polymers to make the essential battery components consisting of the separator, electrolyte, and anode/cathode. The battery cells also use chemicals and specialty chemicals that must be at rigorous purity levels for preparing the casing, filling operations, and preparing slurries. The battery pack will have micro-electronics and automotive components and require cleanliness monitoring.

Pall Corporation is your partner for filtration and separation needs and has experience throughout the EV battery value chain. Pall has over 400 qualified Engineers and Scientists that can provide: prototype testing, on site pilot testing, best practice training, process optimization, audits, contaminant analysis, application troubleshooting, validation services, presentations at scientific forums, and journal publications.

Figure 3. Applications in the EV Battery Value Chain

Supporting the EV revolution from the mine
Mining operations typically involve the quarrying of the lithium rich ore from the surrounding rock followed by crushing & grinding operations, bulk separation by gravity difference or flotation and transport. Various mechanical operations are involved including crusher machines, mechanical shovels, large capacity haul trucks, transport belts, control systems, rotating equipment, and remote generators. Water treatment and fuel conditioning are also essential to the mining operation. Separation applications in mining are described in Table 1 for hydraulic fluids, lube oil fluids, diesel and process fluids, and water treatment.
